1. Limiting density of interpolation nodes:

   - Suppose $x_0, x_1, \ldots, x_n$ are $n+1$ points equally spaced from -1 to 1. If $-1 \leq a < b \leq 1$, what fraction of points lie in the interval $[a, b]$ in the limit as $n \to \infty$?
     Solution: $\dfrac{b-a}{2n}$ ∎

   - Give the analogous expression for the case where $x_0, x_1, \ldots, x_n$ are Chebyshev nodes.
     Solution: The Chebyshev nodes are given by $\cos\left(\dfrac{j\pi}{n}\right)$, where $j \in \{0, 1, 2, \ldots, n\}$. Hence, the number of points is
     $$\frac{\frac{n}{\pi}\left(\lfloor\arccos(a)\rfloor - \lceil\arccos(b)\rceil\right)}{n} = \frac{\left(\lfloor\arccos(a)\rfloor - \lceil\arccos(b)\rceil\right)}{\pi} \quad ∎$$

   - Obtain in the limit as $n \to \infty$, the density of Chebyshev points at $x \in (-1, 1)$. The density is defined as
     $$\rho(x) = \lim_{\epsilon \to 0} \lim_{n \to \infty} \frac{\frac{\text{Number of Chebyshev nodes in the interval } (x-\epsilon, x+\epsilon)}{2\epsilon}}{n}$$
     Solution:
     $$\lim_{\epsilon \to 0} \frac{1}{\pi} \frac{\arccos(x-\epsilon) - \arccos(x+\epsilon)}{2\epsilon} = \frac{1}{\pi\sqrt{1-x^2}}$$
     ∎

2. Recall that we interpolated a function $f(x)$ on a set of $n+1$ distinct points
   $$x_0 < x_1 < \cdots < x_n$$
   using Lagrange polynomials as $p_n(x) = \sum_{j=0}^{n} y_j L_j(x)$, where y_j is the value of the function $f(x)$ at x_j and $L_j(x)$ is the Lagrange polynomial taking a value of 1 at $x = x_j$ and 0 elsewhere. To obtain the derivative of $p_n(x)$ at the data points x_j, we seek a matrix D such that
   $$Dy = p'_n$$
   where y is the vector of function values and p'_n is a vector of derivatives at x_j.

   - Show that $d_{jk} = \left.\dfrac{dL_k(x)}{dx}\right|_{x=x_j}$
     Solution: We have $\dfrac{d}{dx}(p_n(x)) = \sum_{j=0}^{n} y_j \dfrac{dL_j(x)}{dx} \implies \left.\dfrac{d}{dx}(p_n(x))\right|_{x=x_k} = \sum_{j=0}^{n} y_j \left.\dfrac{dL_j(x)}{dx}\right|_{x=x_k}$ ∎

   - Obtain an expression for d_{jk} in terms of x_i's.
     Solution: $d_{jk} = \dfrac{\alpha_k}{\alpha_j(x_j - x_k)}$ for $j \neq k$, where $\alpha_j = \left(\displaystyle\prod_{i=0, i\neq j}^{n}(x_j - x_i)\right)^{-1}$ ∎

3. A general Pade type boundary scheme (at $i = 0$) for the first derivative can be written as
   $$f'_0 + \alpha f'_1 = \frac{af_0 + bf_1 + cf_2 + df_3}{h}$$

   - Obtain a, b, c, d in terms of α, if we would like the scheme to be third order accurate.
     Solution: $a = -\dfrac{11 + 2\alpha}{6}$, $b = \dfrac{6-\alpha}{2}$, $c = \dfrac{2\alpha - 3}{2}$, $d = \dfrac{2-\alpha}{6}$ ∎

   - What value of α you would pick and why?
     Solution: Pick $d = 0$, so that the stencil would be more compact, i.e., pick $\alpha = 2$. ∎

   - Find all the coefficients if such a scheme would be fourth-order accurate.

4. The integral $\int_0^\pi \sin(x)dx$ is approximated using Trapezoidal rule with $N+1$ points and a grid spacing of $\dfrac{\pi}{N}$, say T_n is the approximation.

   - Obtain an expression for T_N as a function of N.

     Solution: The grid points are $x_j = \dfrac{j\pi}{N}$. Hence, we have

     $$T_N = \frac{\pi}{N}\sum_{j=1}^{N-1}\sin\left(\frac{j\pi}{N}\right) = \frac{\pi}{N}\frac{\sin\left((N-1)\pi/(2N)\right)}{\sin\left(\pi/(2N)\right)}\sin\left(\frac{\pi}{2}\right) = \frac{\pi}{N}\cot\left(\pi/(2N)\right)$$

     ∎

   - Compute the value of $\lim_{N\to\infty}T_N$ and check if it gives the exact integral.
     Solution: Limiting value of T_N is 2, which indeed matches with the integral. ∎

5. One would like to derive a Runge Kutta method of order 3. Recall that RK3 method is given by

   $$y_{n+1} = y_n + h\sum_{i=1}^{3}\gamma_i k_i$$

   $$k_1 = f(t_n, y_n)$$
   $$k_2 = f\left(t_n + \alpha_1 h, y_n + h\beta_{21}k_1\right)$$
   $$k_3 = f\left(t_n + \alpha_2 h, y_n + h\beta_{31}k_1 + h\beta_{32}k_2\right)$$

   Obtain the constraints on γ_i, α_i and β_{ij}.

6. Obtain the stability region and accuracy for the weighted trapezoidal rule:

   $$y_{n+1} = y_n + h\left(\alpha f\left(t_n, y_n\right) + (1-\alpha) f\left(t_{n+1}, y_{n+1}\right)\right)$$

   where $\alpha \in (0,1)$.

7. We have access to a uniform random number generator on the interval $[0,1]$. Let's call this function rand(), i.e., calling $x = \text{rand}()$ will give us a number on the interval $[0,1]$ generated out of a uniform distribution on the interval $[0,1]$. Use this random number generating function to generate

   - A Bernoulli random variable Z, i.e., the random variable Z takes only two values 0 or 1. It takes value 0 with a probability p and a value 1 with a probability $1-p$.
     Solution: Let U be the uniform random variable generated by rand() on the interval $[0,1]$. Consider the random variable Z which takes value 0, when rand() $\leq p$ and value 1, when rand() $> p$. Now probability that Z takes 0 is same as the probability that a uniform random variable on the interval $[0,1]$ is less than p, which is nothing but p, i.e.,

     $$\mathbb{P}\left(Z=0\right) = \mathbb{P}\left(U \leq p\right) = p$$

     $$\mathbb{P}\left(Z=1\right) = \mathbb{P}\left(U > p\right) = 1 - p$$

     ∎

   - A Binomial random variable Y with parameters n and p, i.e., a random variable which takes values belonging to $\{0,1,2,\ldots,n\}$, whose probability mass function is given by

     $$P_Y(y=k) = \binom{n}{k}p^k\left(1-p\right)^{n-k} \quad \text{for } k \in \{0,1,2,\ldots,n\}$$

     Solution: A binomial random variable with parameters n and p is a sum of n Bernoulli random variable with parameter p. Hence, generate n Bernoulli random variables $Z_1, Z_2, \ldots, Z_n$. Set the binomial random variable as $Z_1 + Z_2 + \cdots + Z_n$. ∎

8. We have access to a uniform random number generator on the interval $[0, 1]$. Let's call this function rand(), i.e., calling $x = \text{rand}()$ will give us a number on the interval $[0, 1]$ generated out of a uniform distribution on the interval $[0, 1]$. Describe a prodecure to use this random number generating function to obtain the value of the integral

$$\int_1^\infty \frac{dx}{1 + x^2}$$

Solution: Use a change of variables $x = 1/t$. We then see that the integral becomes

$$\int_0^1 \frac{dt}{1 + t^2}$$

Now generate n uniform random numbers on the interval $[0, 1]$, say $\{t_i\}_{i=1}^n$, and approximate the integral as

$$\frac{\sum_{i=1}^n \frac{1}{1 + t_i^2}}{n}$$

∎
